# IMAGING APPARATUS AND IMAGING METHOD WHICH PERFORM FOCUS ADJUSTMENT WHILE PERFORMING LIVE-VIEW DISPLAY

Benefit is claimed, under 35 U.S.C. §119, to the filing date of prior Japanese Patent Application No. 2013-085772 filed on Apr. 16, 2013. This application is expressly incorporated herein by reference. The scope of the present invention is not limited to any requirements of the specific embodiments described in the application.

## BACKGROUND OF THE INVENTION

### 1. Field of the Invention

The present invention relates to an imaging apparatus and an imaging method which perform focus adjustment while performing live-view display.

### 2. Description of Related Art

There has been known a camera which performs exposure by setting an exposure parameter (exposure time, aperture value, etc.) calculated based on brightness in a predetermined photometric area of a subject, when performing normal live-view display without performing focus adjustment (hereinafter, such exposure is called "LVAE"), and which performs the exposure for obtaining image data for the focus adjustment by selecting a photometric area for the focus adjustment (hereinafter, called "AFAE") and also uses the image data obtained based on this AFAE in parallel for the live-view display, when performing the live-view display together with focus adjustment. However, since generally a photometric range for the case of performing the focus adjustment is frequently narrower than the photometric range for the case of performing the normal live-view display, even for image data on the same subject area, between the image data for the focus adjustment and the image data for the normal live-view display, not only the level of the image data is different but also the brightness distribution mode of the image is frequently different because of saturation of the image data. Accordingly, the image quality of the live-view display changes between before and after the focus adjustment and a user feels uncomfortable.

Japanese Patent No. 2010-68046 (hereinafter, called "Patent Literature 1") solves a problem as described above by correcting the image data for the focus adjustment so as to cause the levels of the image data to become close to each other between the focus adjustment and the normal live-view display.

## SUMMARY OF THE INVENTION

In Patent Literature 1, the level of the captured image data is different between before and after release operation, even for the same subject part. For example, when, although the image data obtained by performing LVAE for some subject area does not reach a saturation level, the image data obtained by performing AFAE for the same subject area reaches the saturation level, it is not possible to correct the image data obtained by AFAE into the image data having the same image quality as that of the image data obtained by LVAE. Accordingly, in such a case, even when the image data is corrected, the image quality of the live-view display still changes between before and after the focus adjustment, and thus the user feels uncomfortable.

The present invention has been achieved in view of such a situation, and aims to provide an imaging apparatus and an imaging method which perform the live-view display by generating the image data using the exposure parameter calcu-

2

lated from the brightness value of the photometric area for the live-view display which is different from the photometric area for the focus adjustment when not performing the focus adjustment, and also can perform the focus adjustment in a high accuracy while performing the live-view display in a preferable image quality despite whether the focus adjustment is being performed or not when performing the live-view display also during the focus adjustment.

An imaging apparatus according to the present invention is an imaging apparatus performing live-view display by generating image data using an exposure parameter calculated from a brightness value in a photometric area for the live-view display which is different from the photometric area for focus adjustment when not performing the focus adjustment, and performing the live-view display also when performing the focus adjustment, and includes: a focus adjustment brightness value calculation section comparing a first brightness value in the photometric area for the live-view display with a second brightness value in the photometric area for the focus adjustment, correcting the first brightness value according to a comparison result, and calculating a brightness value for obtaining the image data for the focus adjustment; an imaging section obtaining the image data by performing exposure using the brightness value calculated by the focus adjustment brightness value calculation section; a focus adjustment section performing the focus adjustment using the image data obtained by the imaging section; and a display section performing the live-view display using the image data obtained by the imaging section.

An imaging method according to the present invention is an imaging method performing live-view display by generating image data using an exposure parameter calculated from a brightness value in a photometric area for the live-view display which is different from the photometric area for focus adjustment when not performing the focus adjustment, and performing the live-view display also when performing the focus adjustment, and includes the steps of: comparing a first brightness value in the photometric area for the live-view display with a second brightness value in the photometric area for the focus adjustment, correcting the first brightness value according to a comparison result, and calculating a brightness value for obtaining the image data for the focus adjustment; obtaining the image data by performing exposure using the calculated brightness value; performing the focus adjustment using the obtained image data; and performing the live-view display using the obtained image data.

## BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a block diagram mainly showing an electrical configuration of a camera according to Embodiments 1 to 3.

FIG. 2 is a flowchart showing an operation flow of camera control according to Embodiment 1 to 3.

FIG. 3 is a subroutine showing a flow of LVAE processing of a camera according to Embodiments 1 to 3.

FIG. 4 is a subroutine showing a flow of LVAE-AFAE exposure difference suppression processing in a camera according to Embodiment 1.

FIG. 5 is a subroutine showing a flow of AFAE processing of a camera according to Embodiments 1 to 3.

FIGS. 6A to 6C show an example of photometric areas and a focus area in the whole imaging area according to Embodiments 1 to 3, in which FIG. 6A is a diagram showing the focus area, FIG. 6B is a diagram showing the photometric area for LVAE, and FIG. 6C is a diagram showing the photometric area including the focus area.

3

FIG. 7 is a graph showing a relationship between a difference of the brightness of a focus adjustment photometric area from the brightness of a live-view display photometric area (delta\_bv) and a correction value for correcting the brightness value of the live-view display photometric area to calculate a brightness value for performing focus adjustment (bv\_revise), in Embodiment 1.

FIG. 8 is a graph showing a relationship between a difference of the brightness of a focus adjustment photometric area from the brightness of a live-view display photometric area (delta\_bv) and a correction value correcting the brightness value of the live-view display photometric area to calculate a brightness value for performing focus adjustment (bv\_revise), in Embodiment 2.

FIG. 9 is a graph showing a relationship between a difference of the brightness of a focus adjustment photometric area from the brightness of a live-view display photometric area (delta\_bv) and a correction value correcting the brightness value of the live-view display photometric area to calculate a brightness value for performing focus adjustment (bv\_revise), in Embodiment 3.

#### DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

##### Embodiment 1

In the following, preferred Embodiment 1 will be explained by the use of a camera to which the present invention is applied. Note that, in the following explanation, explanation or detailed explanation will be omitted for the same operation and control technique as those of a typical imaging apparatus.

A camera according to Embodiment 1 is a digital camera, includes an imaging element 105, converts a subject image into image data in this imaging element 105, and displays the subject image on a display section in real time (hereinafter, called "live-view display") according to this converted image data. In photographing, a photographer selects an area where a subject is to be focused (hereinafter, called "focus area") and determines composition by observing the live-view display. When a release button included in an operation section 114 is half-pressed (hereinafter, called "1st release"), the focus of a photographic lens 100 is adjusted, and, when the release button is further pressed fully (hereinafter, called "2nd release"), photographing is performed. The image data obtained in the photographing is recorded into a memory 111 after having been subjected to predetermined image processing in an image processing circuit 110.

FIG. 1 is a block diagram mainly showing an electrical configuration of the camera according to Embodiment 1. The camera according to Embodiment 1, when broadly divided, includes a lens unit 10, and a camera body 20. The lens unit 10 includes the photographic lens 100, a diaphragm 101, a lens/diaphragm drive motor 102 for the driving thereof, a motor drive circuit 103, and a lens-side CPU 104. Further, the camera body 20 includes the imaging element 105, an imaging-control/signal-processing circuit 106, a camera-side CPU 107, an AF (Auto Focus) estimation value calculation circuit 108, an AE (Auto Exposure) estimation value calculation circuit 109, the image processing circuit 110, the memory 111, a display circuit 112, a display section 113, the operation section 114, and a recording medium 115.

The photographic lens 100 is configured with plural optical lenses for forming a subject image, and is a single focus lens or a zoom lens. The diaphragm 101 is disposed on an optical axis of the photographic lens 100 around an exit pupil of the

4

photographic lens 100, and adjusts incident light intensity and focal depth. The diaphragm 101 and the photographic lens 100 are controlled by the camera-side CPU 107, the lens-side CPU 104, the motor drive circuit 103, and the motor 102, and focus adjustment and aperture adjustment are realized. Here, the lens-side CPU 104 interprets a control command received from the camera-side CPU 107 to be described below, and controls the lens 100 and the diaphragm 101.

The imaging element 105 is disposed on the optical axis of the photographic lens 100, and performs the imaging of a subject image formed by the photographic lens 100. This imaging element 105 is configured with pixels which include photodiodes and are arranged in a two-dimensional matrix, and stores electric charge according to received light intensity. Electric charge storage control, image signal read-out control, and the like of the imaging element 105 are performed by the imaging-control/signal-processing circuit 106 connected to the output of the imaging element 105. The image data read out from this imaging element 105 is output to the camera-side CPU 107, the AF estimation value calculation circuit 108, the AE estimation value calculation circuit 109, the image processing circuit 110, and the memory 111.

The AF estimation value calculation circuit 108 detects a focusing state of a subject using a high-frequency component of the image data output from the imaging element 105. This AF estimation value calculation circuit 108 is used also as a focus adjustment section. The AE estimation value calculation circuit 109 calculates a brightness value when the focus adjustment image data is obtained, by correcting a brightness value of the photometric area when the live-view image data is obtained, and calculates an exposure time (Tv) and an aperture value (Av) for obtaining appropriate exposure in the live-view display and in the focus adjustment. This AE estimation value calculation circuit 109 is used also as a focus adjustment brightness value calculation section. The image processing circuit 110 performs various kinds of image processing such as synchronization processing, gradation conversion processing, white balance adjustment, edge processing, for the image data read out from the imaging element 105. The image data subjected to the image processing is recorded into the recording medium 115 mounted on the camera body 20 detachably.

When the user operates the operation section 114 connected to the camera-side CPU 107, the AF estimation value calculation circuit 108, the AE estimation value calculation circuit 109, the image processing circuit 110, and the memory 111 are controlled by the camera-side CPU 107, and the focus adjustment, the exposure control, the image processing, and the like are performed as basic operations of the camera. At this time, in operation accompanying the control of the lens and the diaphragm such as AF and AE, the camera-side CPU 107 transmits a control command to the lens-side CPU 104 according to a control program stored in the memory 111, using output values of the AF estimation value calculation circuit 108 and the AE estimation value calculation circuit 109. Further, the camera-side CPU 107 displays a live-view image expressed by the display image data generated in the image processing circuit 110, on the display section 113 via the display circuit 112.

Next, a specific operation flow of the present invention using the above described electrical configuration will be explained with reference to flowcharts in FIG. 2 to FIG. 5. Note that, in the explanation of the following operation, each of the operations is performed by the camera-side CPU 107 as far as not mentioned otherwise in particular.

FIG. 2 is a flowchart showing an operation flow of the camera control according to Embodiment 1. First, in step S21,

5

the camera-side CPU 107 obtains Bv for LVAE (Brightness value) (variable name: lvae\_bv) which is a brightness value of a photometric area for the normal live-view display without the focus adjustment. This lvae\_bv is calculated in the AE estimation value calculation circuit 109 by so-called apex calculation based on an average level of the image data of the LVAE photometric area in the image data obtained by the imaging of the imaging element 105.

At this time, a scene as shown in FIG. 6A is assumed. In an example shown in FIG. 6A, a house Sub1 (part provided with hatching) on the right side of a screen has a low brightness because of a shadow area, and a background Sub2 including mountains has a high brightness because of the sunshine. The main subject is a person and a focus area F1 is set at a face part.

FIG. 6B shows the LVAE photometric area M-LVAE in the live-view display, and this area is set across a wide range as shown in FIG. 6B. Since most of the LVAE photometric area M-LVAE has a high brightness in the scene shown in FIG. 6B, lvae\_bv has a large value. LVAE processing is performed using this lvae\_bv in step S22. This LVAE processing performs appropriate exposure control for live-view by calculating and setting an exposure condition using lvae\_bv.

Next, the LVAE processing in step S22 will be explained in detail with reference to a subroutine in FIG. 3. This LVAE processing is executed by a cooperative operation of the AE estimation value calculation circuit 109 and the camera-side CPU 107. Step S31 determines Av, Tv, and Sv for LVAE (respective variable names: lvae\_av, lvae\_tv, and lvae\_sv) which are derived from a program chart (not shown in the drawing) using lvae\_bv obtained in step S21.

In step S32, a diaphragm control instruction to cause the diaphragm 101 to provide the value of lvae\_av is transmitted from the camera-side CPU 107 to the lens-side CPU 104. Similarly, in step S33, an imaging element control instruction to cause the imaging element 105 to have an exposure time and a sensitivity of lvae\_tv and lvae\_sv, respectively, is transmitted from the camera-side CPU 107 to the imaging-control/signal-processing circuit 106. The exposure suitable for LVAE is performed by these instructions. After the LVAE processing is finished, the flow returns from the subroutine of FIG. 3.

Next, in step S23 of FIG. 2, it is determined whether the 1st release operation has been performed or not. When it is determined that the 1st release operation has been performed, the flow goes to processing after the 1st release operation in step S24.

Generally, the photometric area for AFAE is different from the photometric area for LVAE. For example, compared with the LVAE photometric area M-LVAE shown in FIG. 6B, the AFAE photometric area M-AFAE which is the photometric area around the focus area shown in FIG. 6C is different in a position and an area size of the photometric area. Accordingly, when the LVAE processing for performing the live-view display is executed using Bv (variable name: afae\_bv) which is a brightness value for AFAE, the image quality of the live-view display is degraded when AF processing is performed. In particular, the image quality of the live-view display changes between before and after the 1st release operation and a user feels uncomfortable. Accordingly, in Embodiment 1, when it is determined that the 1st release operation has been performed, LVAE-AFAE exposure difference suppression processing is performed as described in the following, in step S24.

Next, with reference to FIG. 4, a flow of the LVAE-AFAE exposure difference suppression processing will be explained in detail. Here, this LVAE-AFAE exposure difference sup-

6

pression processing is executed by a cooperative operation of the AE estimation value calculation circuit 109 as a brightness value correction section and the camera-side CPU 107.

In step S41, the camera-side CPU 107 obtains Bv (afae\_a\_bv) which is a brightness value in the AF photometric area around the focus area. Next, in step S42, a difference between afarea\_bv and lvae\_bv (afarea\_bv-lvae\_bv) is calculated to give delta\_bv. Next, in step S43, it is determined whether or not  $\text{track\_limit\_low} \leq \text{delta\_bv} \leq \text{track\_limit\_hi}$  holds. That is, it is determined whether or not delta\_bv is included in a tracking region (upper limit variable: track\_limit\_hi and lower limit variable: track\_limit\_low).

This tracking region is a range of delta\_bv in which an AF accuracy can be secured even if lvae\_bv is used as Bv (variable name: afae\_bv) which is a brightness value for AFAE. When delta\_bv is included in this tracking region, after afae\_bv of Bv for AFAE has been replaced by lvae\_bv in step S44, the flow returns from the LVAE-AFAE exposure difference suppression processing subroutine.

That is, for the case that delta\_bv is included in the tracking region, AFAE after the LVAE-AFAE exposure difference suppression processing becomes the same as LVAE. Accordingly, in the case that delta\_bv is included in the tracking area, the image quality of the live-view display does not change between before and after the 1st release operation is performed. Further, the AF accuracy is also guaranteed.

On the other side, in the case that delta\_bv is not included in the tracking region, if afae\_bv=lvae\_bv, there is a possibility that the AF accuracy cannot be secured. Accordingly, in the case that delta\_bv is not included in the tracking region, a value of lvae\_bv to which a Bv correction value (variable name: bv\_revise) is added as a tracking region excess amount, is used for afae\_bv.

First, in step S45, it is determined whether or not  $\text{track\_limit\_low} > \text{delta\_bv}$  holds. For the case of  $\text{track\_limit\_low} > \text{delta\_bv}$  as the result of this determination, next, in step S46, when the Bv correction value is expressed by bv\_revise, it is determined that  $\text{bv\_revise} = \text{delta\_bv} - \text{track\_limit\_low}$ . On the other side, when it is not determined in step S45 that  $\text{track\_limit\_low} > \text{delta\_bv}$ , it is determined in step S47 that  $\text{bv\_revise} = \text{delta\_bv} - \text{track\_limit\_hi}$ .

After processing of step S46 or step S47 is finished, next, in step S48, the Bv correction value calculated in step S46 or step S47 is added to Bv for LVAE to give afae\_bv. After the calculation of  $\text{afae\_bv} = \text{lvae\_bv} + \text{bv\_revise}$  is performed in step S48, the flow returns from the subroutine of the LVAE-AFAE exposure difference suppression processing.

In this manner, the LVAE-AFAE exposure difference suppression processing (processing of a focus adjustment brightness value calculation section) in the present embodiment calculates the brightness value (afae\_bv) for obtaining image data for the focus adjustment by adding the correction value (bv\_revise) to a first brightness value (lvae\_bv) of the photometric area for the live-view display, and sets the correction value to zero when the brightness difference between the first brightness value and a second brightness value of the photometric area for the focus adjustment is not larger than a predetermined value and increases the correction value as the brightness difference becomes larger when the brightness difference is larger than the predetermined value.

FIG. 7 is a graph showing a relationship between the above described delta\_bv and bv\_revise. In FIG. 7, the horizontal axis shows the difference value (delta\_bv) between the first brightness value (lvae\_bv) for the live-view display and the second brightness value of the photometric area for the focus adjustment, and the vertical axis shows the correction value (bv\_revise). As apparent from FIG. 7, when the difference

7

value (delta\_bv) between the first brightness value (lvae\_bv) of the photometric area M-LVAE for the live-view display and the second brightness value of the photometric area for the focus adjustment is included in the tracking region (track\_limit\_low to track\_limit\_hi), the correction value (bv\_revise) is zero, and, when the difference value (delta\_bv) between the first brightness value (lvae\_bv) and the second brightness value is not included in the tracking region (smaller than track\_limit\_low or larger than track\_limit\_hi), the correction value is determined according to the brightness difference.

In this manner, according to the present embodiment, it is possible to provide an imaging apparatus and an imaging method which can perform the focus adjustment in a high accuracy while performing the live-view display in a preferable image quality despite whether the focus adjustment is being performed or not.

After the LVAE-AFAE exposure difference suppression processing is finished, next, AFAE processing is performed in step S25 of FIG. 2. Next, this AFAE processing will be explained in detail with reference to FIG. 5.

First, in step S51, Av, Tv and Sv for AFAE (respective variable names: afae\_av, afae\_tv, and afae\_sv) derived from a program chart common to LVAE and AFAE are determined using Bv for AFAE (variable name: afae\_bv) obtained in step S24. The above processing is executed by the AE estimation value calculation circuit 109 and the camera-side CPU 107. Next, in step S52, the camera-side CPU 107 transmits the diaphragm control instruction corresponding to afae\_av to the lens-side CPU 104. Next, in step S53, the camera-side CPU 107 transmits the imaging element control instructions corresponding to afae\_tv and afae\_sv to the imaging-control/signal-processing circuit 106.

After the AFAE processing is finished, next, in step S26 of FIG. 2, it is determined whether the 2nd release operation has been performed or not. When the 2nd release operation has not been performed, the flow returns to step S23 and the above described processing is performed repeatedly. When it is determined in step S26 that the 2nd release operation has been performed, next, in step S27, the exposure control is performed using the exposure parameters Av, Tv, and Sv calculated in the above described LVAE processing. This exposure control is executed under a cooperative operation of the camera-side CPU 107, the imaging-control/signal-processing circuit 106, the diaphragm 101, the imaging element 105 and the like. After the exposure control is finished, next, the image data is read out from the imaging element 105 and a predetermined image processing is performed in the imaging-control/signal-processing circuit 106, and the image processing circuit 110. Next, in step S30, the image data is recorded into the recording medium 115.

#### Embodiment 2

Embodiment 2 is different from Embodiment 1 only in the LVAE-AFAE exposure difference suppression processing of step S24 in FIG. 2. The other configuration and processing are the same as those in Embodiment 1, and only the different point will be explained in the following explanation.

FIG. 8 shows a relationship between the difference of the brightness of the focus adjustment photometric area from the brightness of the live-view display photometric area (delta\_bv), and the correction value for correcting the brightness value of the live-view display photometric area to calculate the brightness value for performing the focus adjustment (bv\_revise), in the present embodiment.

8

In the present embodiment, bv\_revise is increased as the absolute value of delta\_bv becomes larger when delta\_bv is included in the range from the lower limit value track\_limit\_low to the upper limit value track\_limit\_hi. That is, lvae\_bv is corrected and afae\_bv is calculated so as to cause the difference between lvae\_bv and afae\_bv to be increased as the absolute value of delta\_bv becomes larger. On the other side, when delta\_bv is not included in the range from the lower limit value track\_limit\_low to the upper limit value track\_limit\_hi, as shown in FIG. 8, it is configured such that the straight line bv\_revise of the vertical axis is inclined to delta\_bv of the horizontal axis by 45 degrees. This means that bv\_revise has a value obtained by subtracting a constant value from delta\_bv. The above processing is executed by a cooperative operation of the AE estimation value calculation circuit 109 as the brightness value correction section and the camera-side CPU 107.

In the present embodiment, when delta\_bv is included in the range from the lower limit value track\_limit\_low to the upper limit value track\_limit\_hi, bv\_revise is increased as the absolute value of delta\_bv becomes larger. Accordingly, compared with Embodiment 1, it is possible to adjust the balance between the accuracy of the focus adjustment and the image quality of the live-view display more delicately.

#### Embodiment 3

Embodiment 3 is different from Embodiment 1 only in the LVAE-AFAE exposure difference suppression processing of step S24 in FIG. 2. The other configuration and processing are the same as those of Embodiment 1, and only the different point will be explained in the following explanation.

FIG. 9 shows a relationship between the difference of the brightness of the focus adjustment photometric area from the brightness of the live-view display photometric area (delta\_bv), and the correction value for correcting the brightness value of the live-view display photometric area to calculate the brightness value for performing the focus adjustment (bv\_revise), in the present embodiment.

In the present embodiment, when delta\_bv is included in the range from the lower limit value track\_limit\_low to the upper limit value track\_limit\_hi, as the absolute value of delta\_bv becomes larger, lvae\_bv is corrected and afae\_bv is calculated so as to cause the difference between lvae\_bv and afae\_bv to be increased. On the other side, when delta\_bv is not included in the range from the lower limit value track\_limit\_low to the upper limit value track\_limit\_hi, the slope of a straight line showing a relationship between delta\_bv and bv\_revise is increased slightly from the slope of the straight line when delta\_bv is included in the range from track\_limit\_low to track\_limit\_hi. This means that lvae\_bv is corrected and afae\_bv is calculated so as to cause the difference between lvae\_bv and afae\_bv to be always increased as the absolute value of delta\_bv becomes larger, in the present embodiment. The above processing is executed by a cooperative operation of the AE estimation value calculation circuit 109 as the brightness value correction section and the camera-side CPU 107.

In this manner, in the LVAE-AFAE exposure difference suppression processing (processing of focus adjustment brightness value calculation section) in the present embodiment, the focus adjustment brightness value calculation section calculates the brightness value (fae\_bv) for obtaining the image data for the focus adjustment by adding the correction value (bv\_revise) to the first brightness value (lvae\_bv) of the live-view display photometric area, and increases the correction value as the brightness difference between the

above described first brightness value (afae\_bv) and the second brightness value of the focus adjustment photometric area (afarea\_bv) becomes larger.

According to the present embodiment, compared with Embodiments 1 and 2, it becomes possible to adjust the balance between the accuracy of the focus adjustment and the image quality of the live-view display more delicately.

The present invention is not limited to the above described embodiments, and can be also realized by modification of the constituents in a range without departing from the gist thereof in the stage of implementation. For example, while, in Embodiment 1, the live-view display is performed based on the image obtained using LVAE before the release operation and the focus adjustment and also the live-view display are performed based on the image data obtained using AFAE after the release operation, the release operation is not necessarily essential. That is, the case that the AF control is performed while the live-view display is being performed is also included in the scope of the present invention. Further, by an appropriate combination of the plural constituents disclosed in the above described embodiments, various inventions can be formed. Further, the constituents across the different embodiments may be combined appropriately. In this manner, various modifications and applications are possible in a range without departing from the gist of the invention.

What is claimed is:

1. An imaging apparatus performing live-view display by generating image data using an exposure parameter calculated from a brightness value in a photometric area for the live-view display which is different from a photometric area for focus adjustment when not performing the focus adjustment, and performing the live-view display also when performing the focus adjustment, the imaging apparatus comprising:

- a first calculating section for calculating a first brightness value in the photometric area for the live-view display;
- a second calculating section for calculating a second brightness value in the photometric area for focus adjustment;
- a comparison section for comparing a brightness difference between the first brightness value and the second brightness value with a specified value;
- a third calculation section correcting the first brightness value according to a comparison result from the comparison section;
- an imaging section obtaining the image data by performing exposure using the brightness value corrected by the third calculation section;
- a focus adjustment section performing the focus adjustment using the image data obtained by the imaging section; and
- a display section performing the live-view display using the image data obtained by the imaging section.

2. The imaging apparatus according to claim 1, wherein the third calculation section calculates a brightness value for obtaining the image data for the focus adjustment by adding a correction value to the first brightness value.

3. The imaging apparatus according to claim 2, wherein the third calculation section sets the correction value to zero when a brightness difference between the first brightness value and the second brightness value is not larger than a predetermined value, and increases the correction value when the brightness difference is larger than the predetermined value.

4. The imaging apparatus according to claim 2, wherein the third calculation section increases the correction value as a brightness difference between the first brightness value and the second brightness value becomes larger.

5. An imaging method performing live-view display by generating image data using an exposure parameter calculated from a brightness value in a photometric area for the live-view display which is different from a photometric area for focus adjustment when not performing the focus adjustment, and performing the live-view display also when performing the focus adjustment, the imaging method comprising the steps of:

- a first step of calculating a first brightness value in a photometric area for the live-view display;
- a second step of calculating a second brightness value in the photometric area for focus adjustment;
- a third step of comparing a brightness difference between the first brightness value and the second brightness value with a specified value;
- a fourth step of correcting the first brightness value according to a comparison result of the third step;
- a fifth step of obtaining the image data by performing exposure using the brightness value corrected in the fourth step;
- a sixth step of performing the focus adjustment using the image data obtained in the fifth step; and
- a seventh step of performing the live-view display using the image data obtained in the fifth step.

6. A method for use in a camera providing live-view display, the method comprising:

- obtaining a live-view auto exposure brightness value;
- determining at least one exposure parameter based on the obtained live-view auto exposure brightness value;
- setting at least one of an aperture value, an exposure time, and an exposure sensitivity of the camera based on the at least one exposure parameter determined;
- receiving a first release signal corresponding to a half-press of a shutter release button; and
- responsive to receipt of the first release signal, obtaining a focus area brightness value, determining a difference between the obtained live-view auto exposure brightness value and the obtained focus area brightness value, determining whether or not the difference is within a predetermined limit range, and responsive to a determination that the difference is not within the predetermined limit range, determining a brightness correction value using a limit of the predetermined limit range and the difference, adding the brightness correction value to the obtained live-view auto exposure brightness value to obtain a corrected brightness value, determining at least one new exposure parameter based on the corrected brightness value, and setting at least one of a new aperture value, a new exposure time, and a new exposure sensitivity of the camera based on the at least one new exposure parameter determined.

7. The method of claim 6 further comprising: receiving a second release signal corresponding to a full-press of a shutter release button; and responsive to receipt of the second release signal, capturing a still image,

wherein the acts of  
obtaining a focus area brightness value,  
determining a difference between the obtained live-  
view auto exposure brightness value and the  
obtained focus area brightness value, 5  
determining whether or not the difference is within a  
predetermined limit range, and  
responsive to a determination that the difference is not  
within the predetermined limit range,  
determining a brightness correction value using a 10  
limit of the predetermined limit range and the  
difference,  
adding the brightness correction value to the  
obtained live-view auto exposure brightness  
value to obtain a corrected brightness value, 15  
determining at least one new exposure parameter  
based on the corrected brightness value, and  
setting at least one of a new aperture value, a new  
exposure time, and a new exposure sensitivity of  
the camera based on the at least one new expo- 20  
sure parameter determined,  
one new exposure parameter determined, are performed  
before the receipt of the second release signal.
